1 Introduction to the Bootstrap

1.1 Required R Packages

We will be using the R packages of:

- boot for help with bootstrapping
- broom for tidy extraction of model components
- tidyverse for data manipulation and visualization

```
library(boot)
library(broom)
library(tidyverse)
```

1.2 Uncertainty in a test statistic

There is often interest to understand the uncertainty in the estimated value of a test statistic.

- For example, let p be the actual/true proportion of customers who will use your company's coupon.
- To estimate p, you decide to take a sample of n=200 customers and find that x=10 or $\hat{p}=10/200=0.05=5\%$ redeemed the coupon.

1.2.1 Confidence Interval

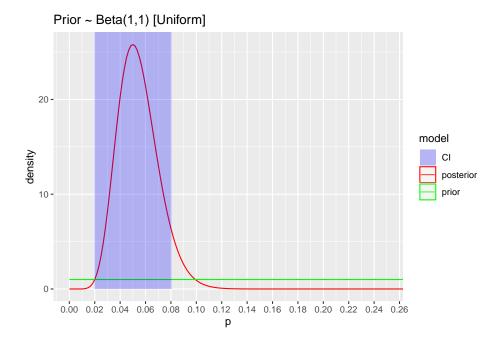

• It is common to calculate the 95% confidence interval (CI)

$$CI(p) = \hat{p} \pm 2 \cdot SE(\hat{p})$$
$$= \hat{p} \pm 2\sqrt{\frac{\hat{p}(1-\hat{p})}{n}}$$
$$= 0.05 \pm 0.03$$

• This calculation is based on the assumption that \hat{p} is approximately normally distributed with the mean equal to the *unknown* true p, i.e., $\hat{p} \sim N(p, \sqrt{\frac{p(1-p)}{n}})$.

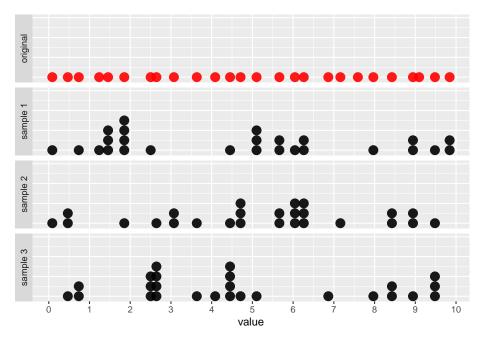

1.2.2 Bayesian Posterior Distribution

In the Bayesian world, you'd probably specify a Beta prior for p, i.e., $p \sim \text{Beta}(a,b)$ and calculate the posterior distribution $p \mid x = 10 \sim \text{Beta}(a+x,b+n-x)$ which would fully characterize the uncertainty.

1.2.3 The Bootstrap

- The Boostrap is a way to assess the uncertainty in a test statistic using resampling.
- The idea is to simulate the data from the *empirical distribution*, which puts a point mass of 1/n at each observed data point (i.e., sample the original data **with replacement**).
 - It is important to simulate n observations (same size as original data) because the uncertainty in the test statistic is a function of n

• Then, calculate the test statistic for each bootstrap sample. The variability in the collection of bootstrap test statistics should be similar to the variability in the test statistic.

Algorithm: Nonparametric/Empirical Bootstrap

Observe data $D = [X_1, X_2, \dots, X_n]$ (*n* observations). Calculate a test statistic $\hat{\theta} = \hat{\theta}(D)$, which is a function of D.

Repeat steps 1 and 2 M times:

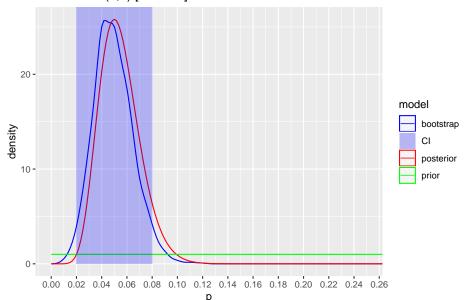

- 1. Simulate D^* , a new data set of n observations by sampling from D with replacement.
- 2. Calculate the bootstrap test statistic $\hat{\theta}^* = \hat{\theta}(D^*)$

The bootstrapped samples $\hat{\theta}_1^*, \hat{\theta}_2^*, \dots, \hat{\theta}_M^*$ can be used to estimate the distribution of $\hat{\theta}$.

• Or properties of the distribution, like standard deviation (standard error), percentiles, etc.

```
#-- Original Data
x = c(rep(1, 10), rep(0, 190))
                              # 10 successes, 190 failures
n = length(x)
                                  # length of observed data
#-- Bootstrap Distribution
                                  # number of bootstrap samples
M = 2000
p = numeric(M)
                                 # initialize vector for test statistic
                                 # set random seed
set.seed(201910)
for (m in 1:M) {
 #- sample from empirical distribution
 ind = sample(n, replace=TRUE) # sample indices with replacement
 xboot = x[ind]
                                # bootstrap sample
 #- calculate proportion of successes
 p[m] = mean(xboot) # calculate test statistic
#-- Bootstrap Percentile based confidence Intervals
quantile(p, probs=c(.025, .975)) # 95% bootstrap interval
#> 2.5% 97.5%
#> 0.02 0.08
```

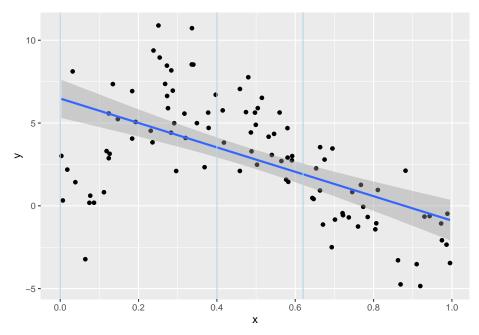

- Notice that in the above example the bootstrap distribution is close to the Bayesian posterior distribution (using the uninformed Uniform prior).
- This is no accident, it turns out there is a close correspondence between the bootstrap derived distribution and the Bayesian posterior distribution under *uninformative priors*
 - See ESL 8.4 for more details

2 Bootstrapping Regression Parameters

The bootstrap is not limited to univariate test statistics. It can be used on multivariate test statistics.

Consider the uncertainty in estimates of the parameters (i.e., β coefficients) of a regression model.

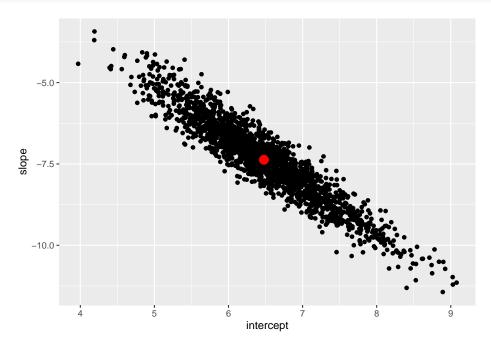

```
data_train = tibble(x,y) # create a data frame/tibble
m1 = lm(y~x, data=data_train) # fit simple OLS
broom::tidy(m1, conf.int=TRUE) # OLS estimated coefficients
#> # A tibble: 2 x 7
#> 1 (Intercept)
               6.48
                     0.584
                              11.1 5.39e-19
                                                    7.64
                      1.06 -6.97 3.69e-10
#> 2 x
              -7.37
                                                    -5.27
vcov (m1)
                      # variance matrix
#>
          (Intercept)
#> (Intercept) 0.3414 -0.5359
              -0.5359 1.1183
```

• The summary () function shows the standard errors of the coefficients.

2.1 Bootstrap the β 's

```
#-- Bootstrap Distribution
M = 2000 # number of bootstrap samples
```

```
beta = matrix(NA, M, 2)
                                # initialize vector for test statistics
set.seed(201910)
                                # set random seed
for (m in 1:M) {
 #- sample from empirical distribution
 ind = sample(n, replace=TRUE) # sample indices with replacement
 data.boot = data_train[ind,]
                               # bootstrap sample
 #- fit regression model
 m.boot = 1m(y~x, data=data.boot) # fit simple OLS
 #- save test statistics
 beta[m, ] = coef(m.boot)
#- convert to tibble (and add column names)
beta = as_tibble(beta, .name_repair = "unique") %>%
 setNames(c('intercept', 'slope'))
#- Plot
ggplot(beta, aes(intercept, slope)) + geom_point() +
 geom_point (data=tibble (intercept=coef (m1) [1],
                      slope = coef(m1)[2]), color="red", size=4)
#- bootstrap estimate
var(beta) # varaince matrix
#> intercept slope
apply(beta, 2, sd) # standard errors (sqrt of diagonal)
#> intercept slope
#> 0.7629 1.2214
```

3 Basis Function Modeling

For a univariate x, a linear basis expansion is

$$\hat{f}(x) = \sum_{j} \hat{\theta}_{j} b_{j}(x)$$

where $b_j(x)$ is the value of the jth basis function at x and θ_j is the coefficient to be estimated. - The $b_j(x)$ are usually specified in advanced (i.e., not estimated)

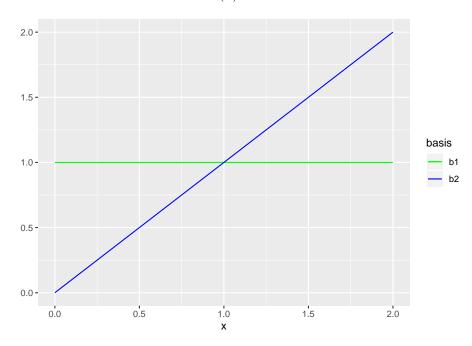

Examples:

• Linear Regression

$$\hat{f}(x) = \hat{\beta}_0 + \hat{\beta}_1 x$$

$$b_1(x) = 1$$

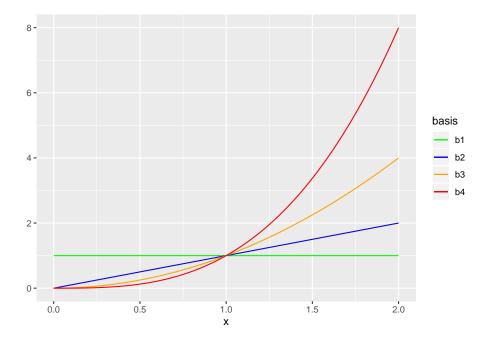

$$b_2(x) = x$$

• Polynomial Regression

$$\hat{f}(x) = \sum_{j=1}^{d} \hat{\beta}_j x^j$$

$$b_j(x) = x^j$$

3.1 Piecewise Polynomials

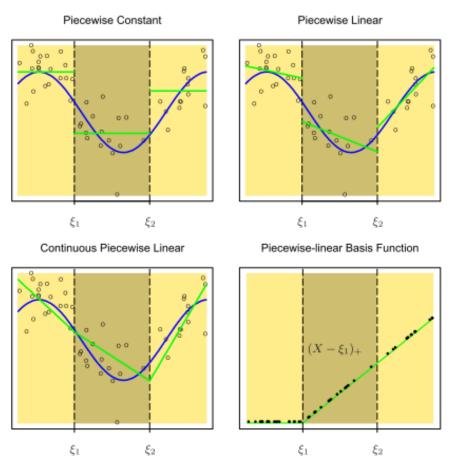

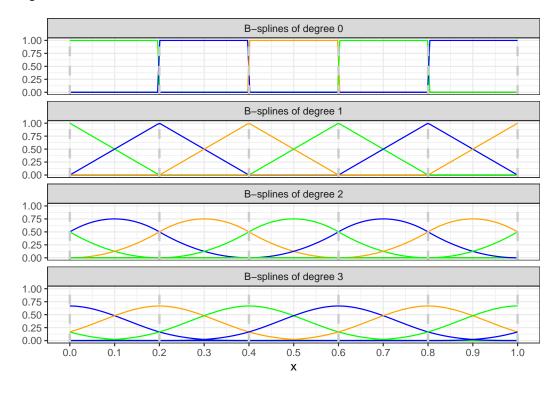

FIGURE 5.1. The top left panel shows a piecewise constant function fit to some artificial data. The broken vertical lines indicate the positions of the two knots ξ_1 and ξ_2 . The blue curve represents the true function, from which the data were generated with Gaussian noise. The remaining two panels show piecewise linear functions fit to the same data—the top right unrestricted, and the lower left restricted to be continuous at the knots. The lower right panel shows a piecewise–linear basis function, $h_3(X) = (X - \xi_1)_+$, continuous at ξ_1 . The black points indicate the sample evaluations $h_3(x_i)$, i = 1, ..., N.

3.2 B-Splines

Like ESL Fig 5.20, B-splines (knots shown by vertical dashed lines)

- A degree = 0 B-spline is a regressogram basis. Will lead to a piecewise constant fit.
- A degree = 3 B-spline (called *cubic* splines) is similar in shape to a Gaussian pdf. But the B-spline has finite support and facilitates quick computation (due to the induced sparseness).

3.2.1 Parameter Estimation

In matrix notation,

$$\hat{f}(x) = \sum_{j} \hat{\theta}_{j} b_{j}(x)$$
$$= R\hat{\theta}$$

where B is the basis matrix.

• For example, a polynomial matrix is

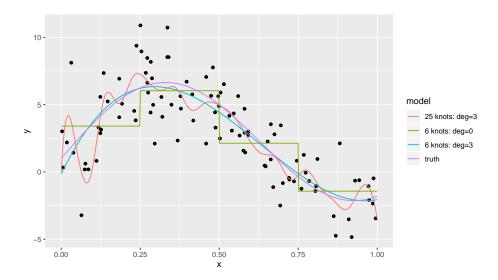

$$B = \begin{bmatrix} 1 & X_1 & \dots & X_1^J \\ 1 & X_2 & \dots & X_2^J \\ \vdots & \vdots & \vdots & \vdots \\ 1 & X_n & \dots & X_n^J \end{bmatrix}$$

• More generally,

$$B = \begin{bmatrix} b_1(x_1) & b_2(x_1) & \dots & b_J(x_1) \\ b_1(x_2) & b_2(x_2) & \dots & b_J(x_2) \\ \vdots & \vdots & \vdots & \vdots \\ b_1(x_n) & b_2(x_n) & \dots & b_J(x_n) \end{bmatrix}$$

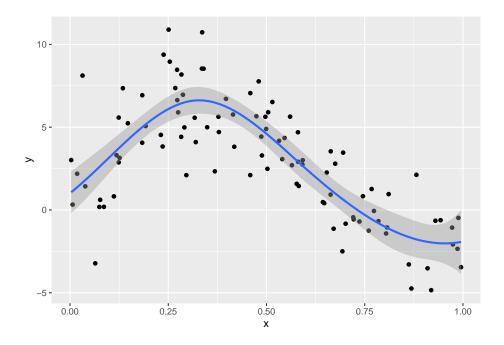

Now, its in a form just like linear regression! Estimate with OLS

$$\hat{\theta} = (B^{\mathsf{T}}B)^{-1}B^{\mathsf{T}}Y$$

- It may be helpful to think of a basis expansion as similar to a dummy coding for categorical variables.
 - This expands the single variable x into df new variables.
- In R, the function bs () can be put directly in formula to make a B-spline.

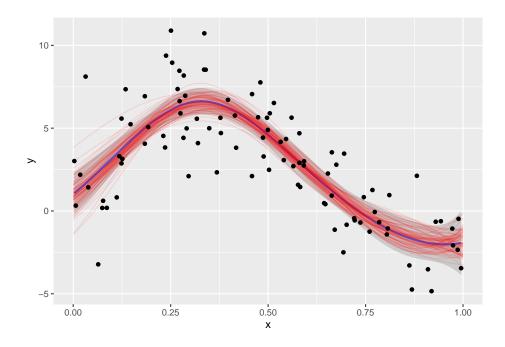

```
#- fit a 5 df B-spline
# Note: don't need to include an intercept in the lm()
# Note: the boundary.knots are set just a bit outside the range of the data
       so prediction is possible outside the range (see below for usage),
       and will lead to equal knot locations during bootstrap.
       You probably won't need to set this in practice.
kts.bdry = c(-.2, 1.2)
model_bs = lm(y \sim bs(x, df=5, deg=3, Boundary.knots = kts.bdry)-1,
             data=data_train)
tidy (model_bs)
#> # A tibble: 5 x 5
#>
    term
                                             estimate std.error statistic p.value
#>
   <chr>
                                              <db1> <db1> <db1> <db1>
                                              -2.50
\#>1 bs(x, df = 5, deg = 3, Boundary.knots =~
                                                         1.51
                                                                  -1.65 1.02e- 1
\#> 2 \text{ bs}(x, df = 5, deg = 3, Boundary.knots =~ 10.9
                                                         1.27
                                                                  8.61 1.53e-13
\#> 3 bs(x, df = 5, deg = 3, Boundary.knots =~ -0.241
                                                         1.53
                                                                  -0.157 8.76e- 1
\#>4 bs(x, df = 5, deg = 3, Boundary.knots =~ -4.71
                                                         3.07
                                                                  -1.53 1.28e- 1
\#>5 bs(x, df = 5, deg = 3, Boundary.knots =~
                                              1.45
                                                         6.90
                                                                  0.211 8.34e- 1
ggplot(data_train, aes(x,y)) + geom_point() +
 geom_smooth(method='lm', formula='y~bs(x, df=5, deg=3, Boundary.knots = kts.bdry)-1')
```

3.3 Bootstrap Confidence Interval for f(x)

Bootstrap can be used to understand the uncertainty in the fitted values

```
#-- Bootstrap CI (Percentile Method)
M = 100
                                            # number of bootstrap samples
data_eval = tibble(x=seq(0, 1, length=300)) # evaluation points
YHAT = matrix(NA, nrow(data_eval), M)
                                           # initialize matrix for fitted values
#-- Spline Settings
for (m in 1:M) {
 #- sample from empirical distribution
 ind = sample(n, replace=TRUE)
                                            # sample indices with replacement
 #- fit bspline model
 m_boot = lm(y \sim bs(x, df=5, Boundary.knots=kts.bdry)-1,
             data=data_train[ind,])
                                     # fit bootstrap data
 #- predict from bootstrap model
 YHAT[,m] = predict(m_boot, newdata=data_eval)
}
#-- Convert to tibble and plot
data_fit = as_tibble(YHAT) %>%
 bind_cols(data_eval) %>% # add the eval points
  gather(simulation, y, -x)
                              # convert to long format
ggplot(data_train, aes(x,y)) +
  geom_smooth (method='lm',
              formula='y~bs(x, df=5, deg=3, Boundary.knots = kts.bdry)-1') +
  geom_line(data=data_fit, color="red", alpha=.10, aes(group=simulation)) +
  geom_point()
```

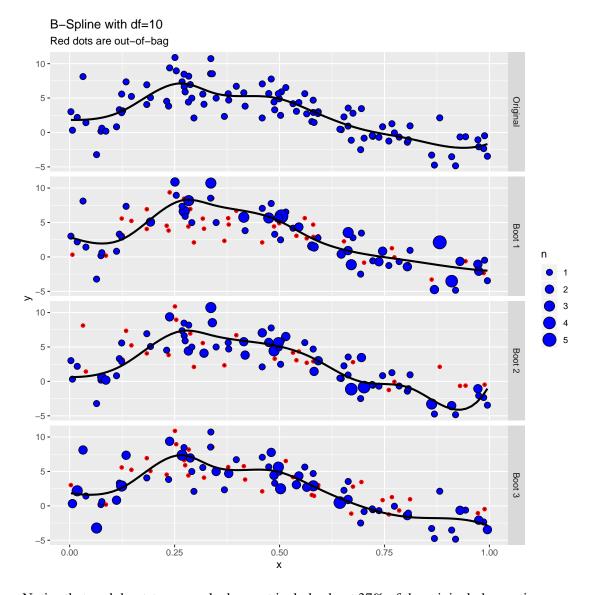

4 More Bagging

4.1 Out-of-Bag Samples

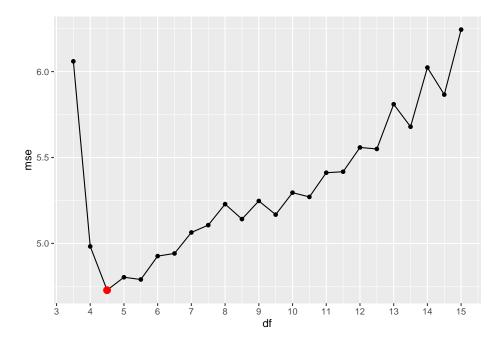

Your Turn #1: Observations not in bootstrap sample What is the expected number of observations that will *not* be in a bootstrap sample? Suppose *n* observations.

Let's look at a few bootstrap fits:

SYS 6018 | Fall 2019

- Notice that each bootstrap sample does not include about 37% of the original observations.
- These are called *out-of-bag* samples and can be used to assess model fit
 - The out-of-bag observations were not used to estimate the model parameters, so will be sensitive to over/under fitting
- Below, we evaluate the oob error over the spline complexity (df = number of estimated coefficients)

4.2 Number of Bootstrap Simulations

Hesterberg recommends using $M \ge 15{,}000$ for real applications to remove most of the Monte Carlo variability.

• For the examples in class I used much less to demonstrate the principles.

5 More Resources

- ESL 5; 8.1-8.4
- ISL 5.2; 7
- The boot package and boot () function provides some more advanced options for bootstrapping
- What Teachers Should Know About the Bootstrap: Resampling in the Undergraduate Statistics Curriculum, by Tim C. Hesterberg
- R's tidymodels package
 - rsample for resampling
 - yardstick for evaluation metrics
 - broom for extracting properties (e.g., estimated parameters) of fitted models in a tidy form

5.1 Variations of the Bootstrap

- We have discussed only one type of bootstrap, *nonparametric/empirical/ordinary* where the observations are resampled
- Another option is to simulate from the *fitted model*. This is called the *parametric* bootstrap.
 - For example, in the regression setting, estimate $\hat{\theta}$ and $\hat{\sigma}$
 - Then given the original X's simulate new $y_i^* \mid x_i \sim f(x_i; \hat{\theta}) + \epsilon(\hat{\sigma})$
